## Jointly constrained semidefinite bilinear programming with an application to Dobrushin curves - Python Code

Stefan Huber, Robert König and Marco Tomamichel

August 9, 2018

The code consists of the following files:

The file tree.py contains the definition of the tree class, which is the main data structure used for the algorithm. The file problem.py implements a solver for bilinear problems, and the file semidefinite.py defines the QuantumBilinearProblem class, which is the class with which the user interacts. The folder examples contains two working examples of the applications we explain below.

We give some examples to show the usage of the QuantumBilinearProblem class.

We assume the following header for all code:

```
from semidefinite import *
from problem import *
import numpy as np
import picos as sdp
import cvxopt as cvx
```

In general, an instance of QuantumBilinearProblem, which we call prob, is created via

```
prob = QuantumBilinearProblem()
```

Then we can initialize the problem by giving the correlation matrices and affine terms (corresponding to Q, A, B in the objective function  $f(X,Y) = \operatorname{tr}((X \otimes Y)Q) + \operatorname{tr}(AX) + \operatorname{tr}(BY)$ ):

```
prob.init_matrix_form(dims, J, A = [], B = [])
```

The syntax for dims is  $[[a_1, a_2, ..., a_r], [b_1, b_2, ..., b_s]]$ . Here, the variables  $X = X_1 \oplus \cdots \oplus X_r$  and  $Y = Y_1 \oplus \cdots \oplus Y_s$  are interpreted as being self-adjoint operators in Hilbert spaces which are direct sums of

qudits  $\mathbb{C}^{a_1} \oplus \cdots \oplus \mathbb{C}^{a_r}$  and  $\mathbb{C}^{b_1} \oplus \cdots \oplus \mathbb{C}^{b_s}$ , respectively. In our implementation, all  $a_i$  and  $b_j$  need to be powers of 2 (in the implementation, we have chosen the Pauli basis and direct sums thereof). It is straightforward to generalize this to qudit systems of arbitrary dimensions by choosing a different basis. The input J is an array of the form  $r \times s$  where every entry  $J_{ij}$  is an  $a_i b_j \times a_i b_j$  matrix which defines the correlations between the i-th X-variable and the j-th Y-variable. Furthermore, A and B are arrays of length r and s, respectively, such that  $A_i$  defines the affine term in the variable  $X_i$  and  $B_i$  defines the affine term in the variable  $Y_i$ . That is, the objective function is

$$f(X,Y) = \sum_{i=1}^{r} \sum_{j=1}^{s} \operatorname{tr}(J_{ij}(X_i \otimes Y_j)) + \sum_{i=1}^{r} \operatorname{tr}(X_i A_i) + \sum_{j=1}^{s} \operatorname{tr}(Y_j B_j) .$$

We will demonstrate this in a concrete example.

Constraints can be added by the routine add\_constraint. Say  $X = X_1 \oplus \cdots \oplus X_r$ , and we want to add the constraint  $0 \le X_j \le I$ . This can be done by adding a constraint on prob.matvarX(j), which is the matrix form of  $X_j$ . prob.matvarY(j) is defined analogously.

```
prob.add_constraint(prob.matvarX(j) >> 0.*np.identity(a_j))
prob.add_constraint(prob.matvarX(j) << np.identity(a_j))</pre>
```

Trace constraints can be added similarly, by using the routine add\_constraint to add constraints on the entries of prob.varX(), which is an array containing the coordinates of  $X_1$  with respect to the Pauli basis, followed by the coordinates  $X_2$  with respect to the Pauli basis, and so on. The array prob.varY() is defined analogously. As an example, consider the case  $b_1 = 2, b_2 = 2$ , and we want to add the constraints  $\operatorname{tr}(Y_1\sigma_3) \leq E$  and  $\operatorname{tr}(Y_2) = 1$ . This can be done via

```
prob.add_constraints(prob.varY()[3] == E/np.sqrt(2))
prob.add_constraints(prob.varY()[4] == 1/np.sqrt(2))
```

Note that we need to add a factor of  $\sqrt{2}$  because we worked with the Pauli basis normalized with respect to the Hilbert-Schmidt inner product.

Finally, the branch-and-bound algorithm to solve the problem can be started by the line

```
prob.solve(verb = 1, maxiter = STD_MAXITER, allowedgap = STD_ALLOWEDGAP)
```

The standard values of maxiter and allowedgap are  $10^5$  and  $10^{-5}$ , respectively. After the algorithm has finished running, we can call the solutions via prob.matsolX(j) and prob.matsolY(j).

## Example: A simple trace distance maximization

Consider the problem

$$\max_{\substack{X,Y \geq 0 \\ \operatorname{tr}(X) = \operatorname{tr}(Y) = 1}} \|X - Y\|_1 = \max_{\substack{X,Y \geq 0 \\ \operatorname{tr}(X) = \operatorname{tr}(Y) = 1}} \max_{\substack{P \in \mathcal{B}_{\operatorname{sa}}(\mathbb{C}^2) \\ 0 \leq P \leq I}} \operatorname{tr}\left(P(X - Y)\right) \ .$$

Note that using the flip operator  $\mathbb{F} = \sum_{i,j=1}^{2} |ij\rangle\langle ji|$ , we can write the objective function in the form

$$\operatorname{tr}(\mathbb{F}(X \otimes P)) - \operatorname{tr}(\mathbb{F}(Y \otimes P))$$
.

It is easy to see that this can also be written as a minimization problem, namely

$$-\min_{\substack{X,Y,P\geq 0\\\operatorname{tr}(X)=\operatorname{tr}(Y)=1\\0\leq P\leq I}}\operatorname{tr}(\mathbb{F}(X\otimes P))-\operatorname{tr}(\mathbb{F}(Y\otimes P))\;.$$

We interpret the variables as follows:  $\mathtt{matvarX}(0)$  plays the role of X,  $\mathtt{matvarX}(1)$  plays the role of Y, and  $\mathtt{matvarY}(0)$  plays the role of P. Hence  $a_1 = a_2 = b_1 = 2$ , and this problem can be solved in the following way:

```
prob = QuantumBilinearProblem()
flip = np.matrix([[1.,0.,0.,0.], [0.,0.,1.,0.], [0.,1.,0.,0.], [0.,0.,0.,1.]])
prob.init_matrix_form([[2, 2], [2]], [[-flip], [flip]])

prob.add_constraint(prob.matvarX(0) >> 0*np.identity(2))
prob.add_constraint(prob.matvarX(1) >> 0*np.identity(2))
prob.add_constraint(prob.matvarY(0) >> 0*np.identity(2))
prob.add_constraint(prob.matvarY(0) << np.identity(2))

prob.add_constraint(prob.varX()[0] == 1./np.sqrt(2))
prob.add_constraint(prob.varX()[4] == 1./np.sqrt(2))

prob.solve(verb = 1)

print('X = ', prob.matsolX(0))
print('Y = ', prob.matsolX(1))
print('P = ', prob.matsolY(0))</pre>
```

The file examples/ex\_tracedist.py contains the full code which implements this problem.

## Example: Computing a qubit Dobrushin curve

As a second example, we show how to compute a point on the Dobrushin curve of a dephasing channel. We recall that this problem is given by

$$F_E(\delta) = \delta \max_{(P,Q,R) \in \Gamma(E,\delta)} \operatorname{tr}(P\Phi(2R-I)) ,$$

where  $\Gamma(E,\delta)$  is the set of triples  $(P,Q,R) \in \mathcal{B}(\mathbb{C}^2)^{\times 3}$  satisfying

$$\begin{split} \operatorname{tr}(Q) &= 1, Q \geq 0, \operatorname{tr}(HQ) \leq E \ , \\ Q + \frac{\delta}{2}(2R - I) \geq 0 \ , \\ \operatorname{tr}(H(Q + \frac{\delta}{2}(2R - I)) \leq E \ , \\ \operatorname{tr}(R) &= 1 \ , \\ 0 \leq R \ , \\ 0 \leq P \leq I \ , \\ \operatorname{tr}(P) &= 1 \ . \end{split}$$

We also recall that the objective function can be recast as

$$\operatorname{tr}(P\Phi(2R-I)) = 2\operatorname{tr}((I\otimes\Phi^*)(\mathbb{F})(P\otimes R)) - \operatorname{tr}(P\Phi(I)) .$$

In the code here,  $\mathtt{matvarX}(0)$  plays the role of R,  $\mathtt{matvarX}(1)$  plays the role of Q, and  $\mathtt{matvarY}(0)$  plays the role of P. For fixed values of and E, which we call  $\mathtt{delt}$  and E in the program, we can solve this problem by the following code:

```
prob = QuantumBilinearProblem()
corr = np.matrix([[1.,0.,0.,0.], [0.,0.,1/2.,0.], [0.,1/2.,0.,0.], [0.,0.,0.,1.]])
prob.init_matrix_form([[2, 2], [2]], [[2.*delt*corr], [0.*corr]],
        A = [], B = [-1.*delt*np.identity(2)])
prob.add_constraint(prob.matvarX(0) >> 0*np.identity(2))
prob.add_constraint(prob.matvarX(1) >> 0*np.identity(2))
prob.add_constraint(prob.matvarX(0) << np.identity(2))</pre>
prob.add_constraint(prob.matvarX(1) + delt*prob.matvarX(0) >> delt/2.*np.identity(2))
prob.add_constraint(prob.matvarY(0) >> 0*np.identity(2))
prob.add_constraint(prob.matvarY(0) << np.identity(2))</pre>
prob.add_constraint(prob.varX()[0] == 1./np.sqrt(2.))
prob.add_constraint(prob.varX()[4] == 1./np.sqrt(2.))
prob.add_constraint(prob.varX()[7] == E/np.sqrt(2.))
prob.add_constraint(prob.varX()[7] + delt*prob.varX()[3] == E/np.sqrt(2.))
prob.add_constraint(prob.varY()[0] == 1./np.sqrt(2.))
prob.solve(verb = 1)
```

The file examples/ex\_dobrushin.py contains the full code which implements this problem.
